

Background:

Analog Hall Effect detectors can measure the strength of a magnetic field created by a polarized object. By connecting this detector to an Arduino, we can measure the magnetic field.

Sketch:

The sketch folder contains the simple code for reading the hall detector output, the output can be read on an external device by shared serial port.

PYTHON:

The attached python code is broken into two parts, the first collects data from the Arduino and creates the csv files. The second part converts the recorded voltages in the .csv file to relative magnetic field strength and plots the data.

FIGURES:

This folder contains the resultant figures from the python script.
